

# Bounding Volume Hierarchies

Matthias Müller, Ten Minute Physics

[matthiasmueller.info/tenMinutePhysics](http://matthiasmueller.info/tenMinutePhysics)

# Problem

- Find all objects overlapping a region

- Region = bounding box of an object  $\rightarrow$  pair collision detection

# Sweep and Prune 2d

- 100 x 100 objects in 2d:  
~ 100 tests per object

# Sweep and Prune 3d

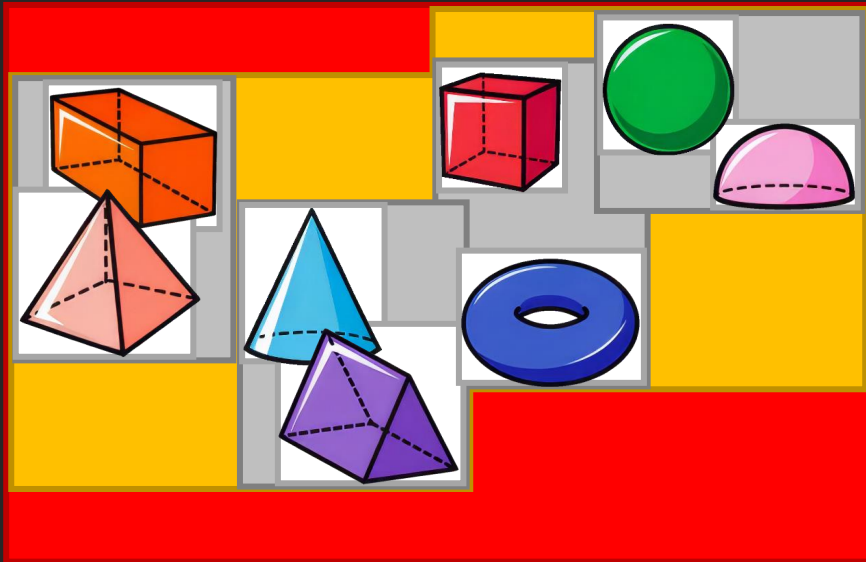

- 100 x 100 x 100 objects in 3d:  
~ 100 x 100 tests per object
- Problem: **uses only one axis**

# Bounding Volume Hierarchy

- $n$  objects:  $\sim \log_2(n)$  tests per object
- 2d: 100 x 100 objects
  - Brute force: 10,000 test per object: 100,000,000 tests
  - SAP:  $\sim 100$  test per object: 1,000,000 tests
  - BVH:  $\sim 13$  test per object: 130,000 tests
- 3d: 100 x 100 x 100 objects
  - Brute force: 1,000,000 1,000,000,000,000 tests
  - SAP:  $\sim 10'000$  test per object: 10,000,000,000 total test
  - BVH:  $\sim 20$  test per object: 20,000,000 total tests

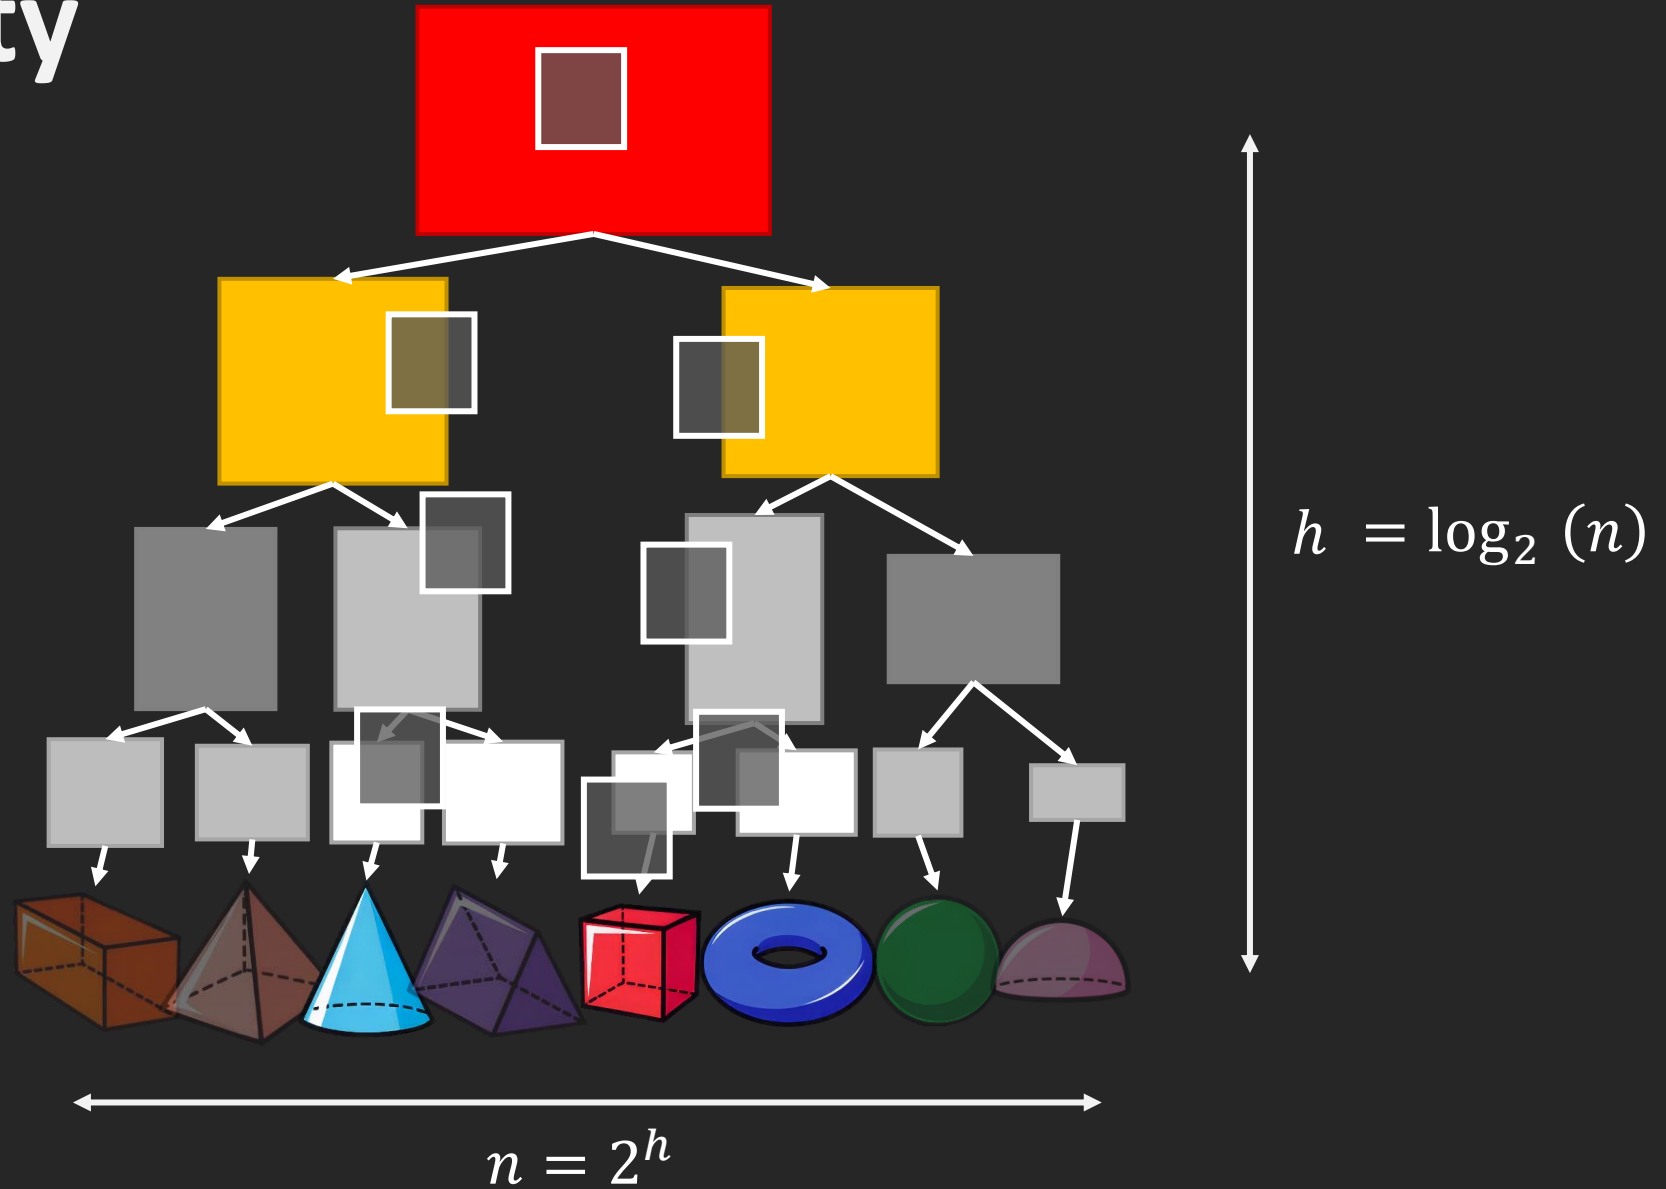

# Data Structure

# Query

# Complexity

# Creation

- Top down:
  - Alternate axes
  - Sort objects, split into equal sets
  - Recurse on both sets

# Dynamic Scenes

- Reorder parts of the tree **dynamically**
  - Complicated, **heterogenous** algorithm
  - Not well suited for parallel implementation
- Reconstruct **from scratch**
  - Every frame
  - Every  $n^{th}$  frame, expand bounds
  - Need of **fast** construction
  - Can we construct the entire tree with one sort?

# Use Integer Coordinates

- Split global bounding box into  $2^b \times 2^b$  virtual cells
- Replace object with center
- Compute integer coordinates

```
let xi = Math.floor((centerX - minX) / (maxX - minX) * (2 ** bits));  
let yi = Math.floor((centerY - minY) / (maxY - minY) * (2 ** bits));
```

# Morton Codes

- For a single sort we need **one** key from **two** coordinates
- **Alternate** axes → **interleave** bits:

# Cell Morton Codes

# Leaf Node

011001

# Resulting Tree

- The Morton code tells us where in the tree we are!

# Splitting

- Sorted Morton codes:

- The highest matching bits define the sub-tree, here **10**
- The highest switching bit determines the cut
- If all keys are equal, split in the middle

# Algorithm

```
class Node { bounds, id, left, right)
```

```
func createTree()
```

```
    list = [{id1, mortonCode1}, {id2, mortonCode2}, ...]
```

```
    sortByMortonCode(list)
```

```
    return createSubTree(list, 1, n)
```

```
func createSubTree(list, begin, end)
```

```
    if begin == end
```

```
        id = list[begin].id
```

```
        return { objectBounds[id], id, null, null }
```

```
    else
```

```
        m = getSplitPos(list, begin, end)
```

```
        left = createSubTree(list, begin, m-1)
```

```
        right = createSubTree(list, m, end)
```

```
        return { union(left.bounds, right.bounds), -1, left, right }
```
